Abstract

(k, s) -SAT is the satisfiability problem restricted to instances where each clause has exactly k literals and every variable occurs at most s times. It is known that there exists a function f such that for $s \leq f(k)$ all (k, s) -SAT instances are satisfiable, but $(k, f(k) + 1)$ -SAT is already NP-complete ($k \geq 3$). The best known lower and upper bounds on $f(k)$ are $\Omega(2^k/k)$ and $O(2^k/k^\alpha)$, where $\alpha = \log_3 4 - 1 \approx 0.26$. We prove that $f(k) = O(2^k \cdot \log k/k)$, which is tight up to a $\log k$ factor.

1 Introduction

We consider CNF formulas represented as sets of clauses, where each clause is a set of literals. A literal is either a variable or a negated variable. Let k, s be fixed positive integers. We denote by (k, s) -CNF the set of formulas F where every clause of F has *exactly* k literals and each variable occurs in *at most* s clauses of F . We denote the sets of satisfiable and unsatisfiable formulas by SAT and UNSAT, respectively.

It was observed by Tovey [7] that all formulas in $(3, 3)$ -CNF are satisfiable, and that the satisfiability problem restricted to $(3, 4)$ -CNF is already NP-complete. This was generalized in Kratochvíl, et al. [4] where it is shown that for every $k \geq 3$ there is some integer $s = f(k)$ such that

1. all formulas in (k, s) -CNF are satisfiable, and
2. $(k, s + 1)$ -SAT, the SAT problem restricted to $(k, s + 1)$ -CNF, is already NP-complete.

The function f can be defined for $k \geq 1$ by the equation

$$f(k) := \max\{s : (k, s)\text{-CNF} \cap \text{UNSAT} = \emptyset\}.$$

Exact values of $f(k)$ are only known for $k \leq 4$. It is easy to verify that $f(1) = 1$ and $f(2) = 2$. It follows from [7] that $f(3) = 3$ and $f(k) \geq k$ in general. Also, by [6], we know that $f(4) = 4$.

Upper and lower bounds for $f(k)$, $k = 5, \dots, 9$, have been obtained in [2, 6, 1, 3]. For larger values of k , the best known lower bound, a consequence of Lovász Local Lemma, is due to Kratochvíl et al. [4]:

$$f(k) \geq \left\lfloor \frac{2^k}{ek} \right\rfloor. \quad (1)$$

The best known upper bound, due to Savický and Sgall [5], is given by

$$f(k) \leq O\left(\frac{2^k}{k^\alpha}\right), \quad (2)$$

where $\alpha = \log_3 4 - 1 \approx 0.26$.

In this paper we asymptotically improve upon (2), and show

$$f(k) = O\left(\frac{2^k \log k}{k}\right). \quad (3)$$

Our result reduces the gap between the upper and lower bounds to a $\log k$ factor. It turns out that the construction yielding the upper bound (3) can be generalized. We present a class of k -CNF formulas, that is amenable to an exhaustive search using dynamic programming. This enables us to calculate upper bounds on $f(k)$ for values up to $k = 20000$ improving upon the bounds provided by the constructions underlying (2) and (3).

The remainder of the paper is organized as follows. In Section 2, we start with a simple construction that already provides an $O(2^k \log^2 k/k)$ upper bound on $f(k)$. In Section 3 we refine our construction and obtain the upper bound (3). In the last section we describe the more general construction and the results obtained using computerized search.

2 The first construction

We denote by $\mathcal{K}(x_1, \dots, x_k)$ the complete unsatisfiable k -CNF formula on the variables $x_1, \dots, x_k$. This formula consists of all 2^k possible clauses. Let $\mathcal{K}^-(x_1, \dots, x_k) = \mathcal{K}(x_1, \dots, x_k) \setminus \{\{x_1, \dots, x_k\}\}$. The only satisfying assignment for $\mathcal{K}^-(x_1, \dots, x_k)$ is the all-False-assignment. Also, for two CNF formulas F_1 and F_2 on disjoint sets of variables, define their product $F_1 \times F_2$ as $\{c_1 \cup c_2 : c_1 \in F_1 \text{ and } c_2 \in F_2\}$. Note that the satisfying assignments for $F_1 \times F_2$ are assignments that satisfy F_1 or F_2 . In what follows, all logarithms are to the base of 2.

Lemma 1. $f(k) \leq 2^k \cdot \min_{1 \leq l \leq k} ((1 - 2^{-l})^{\lfloor k/l \rfloor} + 2^{-l})$.

Proof. We prove the lemma by constructing an unsatisfiable (k, s) -CNF formula F where $s = 2^k \cdot ((1 - 2^{-l})^{\lfloor k/l \rfloor} + 2^{-l})$. Let k, l be two integers such that $1 \leq l \leq k$, and let $u = \lfloor k/l \rfloor$ and $v = k - l \cdot u$. Define the formula F as the union $F = F_0 \cup F_1 \cup \dots \cup F_u$, where:

$$\begin{aligned} F_0 &= \mathcal{K}(z_1, \dots, z_v) \times \prod_{i=1}^u \mathcal{K}^-(x_1^{(i)}, \dots, x_l^{(i)}), \\ F_i &= \mathcal{K}(y_1^{(i)}, \dots, y_{k-l}^{(i)}) \times \{\{x_1^{(i)}, \dots, x_l^{(i)}\}\} \quad \text{for } i = 1, \dots, u. \end{aligned}$$

Therefore, F is a k -CNF formula with n variables and m clauses, where

$$n = k + u \cdot (k - l) \leq l + k^2/l, \quad (4)$$

$$m = 2^v \cdot (2^l - 1)^u + u \cdot 2^{k-l} = 2^k \cdot \left((1 - 2^{-l})^{\lfloor k/l \rfloor} + \lfloor k/l \rfloor \cdot 2^{-l} \right). \quad (5)$$

To see that F is unsatisfiable observe that any assignment satisfying F_0 must set all the variables $x_1^{(i)}, \dots, x_l^{(i)}$ to False for some i . On the other hand, any satisfying assignment to F_i must set at least one of the variables $x_1^{(i)}, \dots, x_l^{(i)}$ to True.

To bound the number of occurrences of a variable note that the variables $z_j, y_j^{(i)}$, and $x_j^{(i)}$ occur $|F_0|$, $|F_i|$, and $|F_0| + |F_i|$ times, respectively. Since $|F_0| = 2^v \cdot (2^l - 1)^u = 2^k \cdot (1 - 2^{-l})^{\lfloor k/l \rfloor}$ and $|F_i| = 2^{k-l}$, we get the required result. □

For $k \geq 4$, let l be the largest integer satisfying $2^l \leq k \cdot \log e / \log^2 k$. It follows that

$$\begin{aligned} (1 - 2^{-l})^{\lfloor k/l \rfloor} &\leq \exp(-2^{-l} \cdot \lfloor k/l \rfloor) \leq \exp\left(-\frac{\log^2 k}{k \log e} \cdot \left(\frac{k}{l} + 1\right)\right) \\ &\leq \frac{1}{\sqrt{e}} \cdot \exp\left(-\frac{\log^2 k}{l \log e}\right) \leq \frac{1}{\sqrt{e}} \cdot \exp\left(-\frac{\log k}{\log e}\right) = \frac{1}{k\sqrt{e}}, \end{aligned}$$

where the last inequality follows from the fact that $l \leq \log k$ for $k \geq 4$. Therefore, by Lemma 1 there exists an unsatisfiable k -CNF formula F where the number of occurrences of variables is bounded by

$$2^k \cdot \left(\frac{1}{k\sqrt{e}} + \frac{2 \log^2 k}{k \log e} \right).$$

It may be of interest that by (4) and (5), the number of clauses in F is $O(2^k \cdot \log k)$ and the number of variables is $O(k^2 / \log k)$.

Corollary 2. $f(k) = O(2^k \cdot \log^2 k / k)$.

3 A better upper bound

To simplify the subsequent discussion, let us fix a value of k . We will only be concerned with CNF formulas F that have clauses of size at most k . We call a clause of size less than k an *incomplete* clause and denote $F' = \{c \in F : |c| < k\}$. A clause of size k is a *complete* clause, and we denote $F'' = \{c \in F : |c| = k\}$.

Lemma 3. $f(k) \leq \min\{2^{k-l+1} : l \in \{0, \dots, k\} \text{ and } l \cdot 2^l \leq \log e \cdot (k - 2l)\}$.

Proof. Let l be in $\{0, \dots, k\}$, satisfying $l \cdot 2^l \leq \log e \cdot (k - 2l)$, and set $s = 2^{k-l+1}$. We will define a sequence of CNF formulas, $F_0, \dots, F_l$. We require that (i) F_j is unsatisfiable, (ii) F_j' is a $(k - l + j)$ -CNF formula, (iii) $|F_j'| \leq 2^{k-l}$, and that (iv) the maximal number of occurrences of a

variable in F_j is bounded by s . It follows that F_l is an unsatisfiable (k, s) -CNF formula, implying the claimed upper bound.

Set $k_j = k - l + j$ and $u_j = \lfloor (k - l + j)/(l - j + 1) \rfloor$. We proceed by induction on j . For $j = 0$, we define $F_0 = \mathcal{K}(x_1, \dots, x_{k-l})$. It can be easily verified that F_0 satisfies the above four requirements. For $j > 0$, assume a formula F_{j-1} on the variables $y_1, \dots, y_n$, satisfying the requirements. We define the formula $F_j = \bigcup_{i=0}^{u_j} F_{j,i}$ as follows:

$$F_{j,0} = \mathcal{K}(z_1, \dots, z_{k_j - u_j \cdot (l-j+1)}) \times \prod_{i=1}^{u_j} \mathcal{K}^-(x_1^{(i)}, \dots, x_{l-j+1}^{(i)}), \quad (6)$$

$$F_{j,i} = F'_{j-1}(y_1^{(i)}, \dots, y_n^{(i)}) \times \{\{x_1^{(i)}, \dots, x_{l-j+1}^{(i)}\}\} \cup F''_{j-1}(y_1^{(i)}, \dots, y_n^{(i)}) \quad \text{for } i = 1, \dots, u_j. \quad (7)$$

It is easy to check that F'_j is a $(k - l + j)$ -CNF formula. To see that F_j is unsatisfiable, observe that any assignment satisfying $F_{j,0}$, must set all the variables $x_1^{(i)}, \dots, x_{l-j+1}^{(i)}$ to False for some i . On the other hand, for any satisfying assignment to $F_{j,i}$, at least one of the variables $x_1^{(i)}, \dots, x_{l-j+1}^{(i)}$ must be set to True.

Let us consider the number of occurrences of a variable in F_j . Consider first the y -variables. These variables occur only in the u_j duplicates of F_{j-1} and therefore occur the same number of times as in F_{j-1} , which is bounded by s by induction. The number of occurrences of an x - or z -variable is $|F'_{j-1}| + |F_{j,0}|$ or $|F_{j,0}|$ respectively. By induction, $|F'_{j-1}| \leq 2^{k-l}$. Also,

$$\begin{aligned} |F'_j| &= |F_{j,0}| = 2^{k_j - u_j \cdot (l-j+1)} \cdot (2^{l-j+1} - 1)^{u_j} = 2^{k_j} \cdot (1 - 2^{-l+j-1})^{u_j} \\ &\leq 2^{k-l+j} \cdot \exp(-2^{-l+j-1} \cdot u_j) \leq 2^{k-l+j} \cdot \exp(-2^{-l+j-1} \cdot (k - 2l)/l). \end{aligned}$$

Taking logarithms, we get

$$\begin{aligned} \log |F_{j,0}| &\leq k - l + j - \log e \cdot 2^{-l+j-1} \cdot (k - 2l)/l \\ &\leq k - l + j - 2^{j-1} \leq k - l. \end{aligned}$$

Therefore, F_l is an unsatisfiable (k, s) -CNF formula for $s = 2^{k-l+1}$, as long as

$$l \cdot 2^l \leq \log e \cdot (k - 2l). \quad (8)$$

□

Let l be the largest integer satisfying $2^l \leq \log e \cdot k/(2 \log k)$. Then (8) holds for $k \geq 2$ and therefore we get the following:

Corollary 4. $f(k) \leq 2^k \cdot 8 \log_e k/k$ for $k \geq 2$.

4 Even better upper bounds

One way to derive better upper bounds on $f(k)$ is to generalize the construction of Section 3. To this end, we first define a special way to compose CNF formulas capturing the essence of that construction.

Definition 5. Let F_1, F_2 be unsatisfiable CNF formulas that have clauses of size at most k such that F'_i is a k_i -CNF formula for $i = 1, 2$. Also, assume that $k_1 \leq k_2 < k$. Then the formula $F_1 \circ F_2$ is defined as:

$$\left(\bigcup_{c \in \mathcal{K}^-(x_1, \dots, x_{k-k_2})} F'_{1,c} \times c \cup F''_{1,c} \right) \cup F'_2 \times \{\{x_1, \dots, x_{k-k_2}\}\} \cup F''_2,$$

where the formulas $F_{1,c}$ are copies of F_1 on distinct sets of variables.

It is not difficult to verify the following:

Lemma 6. Let F_1, F_2 be formulas as above, where the number of occurrences of a variable is bounded by $s \geq (2^{k-k_2} - 1) \cdot |F'_1| + |F'_2|$ and let $G = F_1 \circ F_2$. Then G is an unsatisfiable CNF formula where each variable occurs at most s times. Furthermore, G' is a $(k_1 + k - k_2)$ -CNF formula, and $|G'| = (2^{k-k_2} - 1) \cdot |F'_1|$.

Given k, s , we ask whether we can obtain a k -CNF formula using the following derivation rules. We start with the unsatisfiable formula $\{\emptyset\}$ as an axiom (this formula consists of one empty clause). For a set of derivable formulas, one can apply one of the following rules:

1. If F is a derived formula such that $s \geq 2 \cdot |F'|$, then we can derive $F' \times \{\{x\}, \{\bar{x}\}\} \cup F''$, where x is a new variable.
2. If F_1, F_2 are two derived formulas satisfying the conditions of Lemma 6, then we can derive the formula $F_1 \circ F_2$.

Note 7. One can sometimes replace $F_1 \circ F_2$ in the second rule by a more compact formula $F_1 \circ' F_2$ that avoids duplicating F_1 . Namely, the formula $F'_1 \times \mathcal{K}^-(x_1, \dots, x_{k-k_2}) \cup F''_1 \cup F'_2 \times \{\{x_1, \dots, x_{k-k_2}\}\} \cup F''_2$. Although this can never reduce the number of occurrences of variables, this modification reduces the number of clauses and variables. In the construction of Section 3, we always use $\circ'$ instead of $\circ$.

Since any k -CNF formula obtained using the above procedure is an unsatisfiable (k, s) -CNF, one can define $f_2(k)$ as the maximal value of s such that no k -CNF formula can be obtained using the above procedure (clearly $f(k) \leq f_2(k)$). It turns out that the function $f_2(k)$ is appealing from an algorithmic point of view. Given a value for s , one can check if $f_2(k) \leq s$ using a simple dynamic programming algorithm. For all $l = 0, \dots, k - 1$, the algorithm keeps as state the minimal size of F' for a derivable unsatisfiable formula F where F' is an l -CNF formula. This approach yields an algorithm that works well in practice and we were able to calculate $f_2(k)$ for values up to $k = 20000$ to get the results depicted by the graph in Figure 1.

The computed numerical values of $f_2(k)$ seem to indicate that

$$f_2(k) \cdot k / 2^k = 0.5 \log(k) + o(\log(k)) \quad (9)$$

which is better than our upper bound by a constant factor of about 11. If (9) indeed holds, then a better analysis of the function f_2 may improve our upper bound by a constant factor. However, such an approach cannot improve upon the logarithmic gap left between the known upper and lower bounds on $f(k)$.

Figure 1: The bounds on $f(k) \cdot k / 2^k$. (a) Lower bound of Kratochvíl et al. [4], $1/e$. (b) Upper bound (3) obtained in Section 3 of the present paper, $8 \log_e k$. (c) Upper bound $f_2(k) \cdot k / 2^k$, calculated by a computer program. (d) The line $0.5 \log(k) + 0.23$.
